Coral Reefs In Virgin Islands Facing Warming Waters, Increased Bleaching, N.O.A.A. Says

ST. CROIX -- A new National Oceanic and Atmospheric Administration outlook shows that many coral reefs across around the world will likely be exposed to higher-than-normal sea temperatures for an unprecedented third year in a row, leading to increased bleaching – and with no signs of stopping, according to a press release N.O.A.A. [issued](#) Monday.

But while bleaching is a global phenomenon, it will hit the U.S. hard, especially in Hawaii, Guam, the Commonwealth of the Northern Mariana Islands, Florida Keys, U.S. Virgin Islands and Puerto Rico, according to the release.

"It's time to shift this conversation to what can be done to conserve these amazing organisms in the face of this unprecedented global bleaching event," said Jennifer Koss, NOAA's Coral Reef Conservation Program director. "We have boots on the ground and fins in the water to reduce local stressors. Local conservation buys us time, but it isn't enough. Globally, we need to better understand what actions we all can take to combat the effects of climate change."

NOAA says it's actively working with coastal resource managers and communities in coral reef areas to provide the best available science and tools to enhance reef resilience. The agency and its partners are also developing methods to assess the potential resilience of reefs so management officials can target and prioritize local conservation actions.

This third global coral bleaching event began in mid-2014 is ongoing. Global warming, coupled with an intense El Nino, continues to make this the longest and most widespread coral bleaching event on record. Since its onset, all U.S. coral reefs have seen above normal temperatures and more than 70 percent of them have been exposed to the prolonged high temperatures that can cause bleaching. Studies have shown that about 93 percent of Australia's Great Barrier Reef was bleached as of this April.

"NOAA's satellite and climate models provide us with the ability to track the high temperatures that are causing this bleaching and alert resource managers and scientists around the world," said C. Mark Eakin, NOAA's Coral Reef Watch coordinator. "However, it is crucial that scientists and the public continue on site monitoring of reefs to track the actual extent and severity of the bleaching."

A bleaching event is not always a death sentence for corals. In fact, corals are remarkably resilient creatures. Just as a healthy person is more able to fend off a cold, healthy corals are more likely to resist large-scale stress like a bleaching event. Resilient corals that do bleach have a better chance of recovering if ocean temperatures return to normal relatively quickly and other human impacts are kept at a minimum.

This week, the global bleaching event is on the minds of the world's top coral reef experts as they gather for the 13th International Coral Reef Symposium in Honolulu where the focus is bridging science to policy to achieve coral reef sustainability. Panels and presentations about NOAA's extensive coral reef portfolio will take place throughout the week.

NOAA's Coral Reef Conservation Program was established in 2000 by the Coral Reef Conservation Act to protect, conserve, and restore the nation's coral reefs by maintaining healthy ecosystem function.
